CHARACTERISTICS OF THE GROWTH OF THE DIRECTIONALLY SOLIDIFIED Fe-4.25% C EUTECTIC ALLOY

The current work is dedicated to the mathematical description of a protrusion of the leading phase (cementite) over the wetting phase (austenite) observed during the author’s experiments in previous articles. A cementite protrusion is confirmed in the directionally solidified Fe-4.25% C eutectic alloy. The protrusion is defined due to the mass balance fulfilment. A coordinate system is attached to the solid/liquid interface, which is moving with the constant growth rate $v$.

**Keywords:** Fe-C eutectic alloy, directional solidification, protrusion of leading phase

**Symbols used in the text**

- $C$ – solute concentration in the liquid,
- $C_E$ – solute concentration at the eutectic point,
- $C_0$ – concentration of the cementite at the solubility limit point at temperature $T_E$,
- $C_{Fe(γ)}$ – concentration of the austenite at the solubility limit point at temperature $T_E$,
- $C_{Fe3C}$ – equilibrium solute concentration in the Fe$_3$C – phase lamella,
- $CS_{Fe3C}$ – equilibrium solute concentration in the Fe$_3$C – phase lamella,
- $CS_{Fe(γ)}$ – equilibrium solute concentration in the Fe($γ$) – phase lamella,
- $m$ – slope of liquidus line,
- $m_{Fe3C}$ – slope of liquidus line at the Fe$_3$C phase,
- $m_{Fe(γ)}$ – slope of liquidus line at the Fe($γ$) phase,
- $S_{Fe3C}$ – half the width of the cementite – phase lamellae,
- $S_{Fe(γ)}$ – half the width of the austenite – phase lamellae,
- $T$ – temperature,
- $T_E$ – equilibrium eutectic temperature,
- $tgθ_{Fe3C}$ – tangent of the contact angle of Fe$_3$C phase,
- $tgθ_{Fe(γ)}$ – tangent of the contact angle of Fe($γ$) phase,
- $v$ – growth rate,
- $ΔC_c$ – eutectic difference of the $C_E$ solute concentration and its concentration in the initial alloy,
- $δC$ – concentration field in the liquid ahead the s/l interface,
- $Φ_{Fe3C}$ – volume fraction of the Fe$_3$C phase,
- $Φ_{Fe(γ)}$ – volume fraction of the Fe($γ$) phase,
- $Γ_{Fe3C}$ – capillary length of the Fe$_3$C phase,
- $Γ_{Fe(γ)}$ – capillary length of the Fe($γ$) phase,
- $λ$ – interphase (interlamellar) spacing for regular structure,
- $Π$, $P$ – alloy material constant,
- $ΔT$ – general undercooling,
- $ΔT_{Fe3C}$ – diffusion undercooling of the s/l interface,
- $ΔT_{Fe(γ)}$ – curvature undercooling of the s/l interface,
- $ΔT_{Fe3C}$ – undercooling of the s/l interface of the Fe$_3$C phase,
- $ΔT_{Fe(γ)}$ – undercooling of the s/l interface of the Fe($γ$) phase,
- $θ_{Fe3C}$ – contact angle of Fe$_3$C phase,
- $θ_{Fe(γ)}$ – contact angle of Fe($γ$) phase.
1. Introduction

Eutectics are an archetype of composite materials with a fine microstructure in the μm scale, the properties of which are controlled by solidification conditions. These composites in situ have been studied for decades due to their excellent mechanical properties. In the past, researchers’ attention has focused mainly on metallic eutectics, and most of the progress in understanding eutectic growth and microstructure has been achieved in these materials, [1-5].

The vast majority of technical eutectic alloys consist of two phases. Solidification of double or pseudo-double eutectics may lead to the formation of regular lamellar or fibrous structures, [1,6]. The eutectic growth described by the coupled growth of the solid phase from liquid is an important model for crystal growth, [1,6]. Understanding eutectic growth dynamics is a key aspect of eutectic system research.

Eutectic growth is a typical diffusion controlled process. Therefore, the solution to this problem depends on how to analyse the diffusion field on the solid/liquid interface. The purpose of these analyses is to determine the relationship between undercooling $\Delta T$, growth rate $v$ and interphase spacing $\lambda$.

2. Research material and experimental procedure

The sample of Fe-4.25 wt.% C eutectic alloy, made of high purity Armco and graphite electrodes, was prepared in a corundum crucible under an argon gas shield in a Balzers type heater. After removing the dross and thermal stabilization the molten alloy was cast into a rod of 12 mm diameter. The sample was machined to approximately 5 mm and:

a) placed in an alunode tube (6 mm inner diameter) in the vacuum Bridgman-type furnace, under an argon atmosphere,

b) heated to a temperature of 1450°C,

c) after stabilizing the thermal conditions, lowered from the heating part, at a given rate, to the cooling part of the furnace,

d) grown up to 30 mm in length at a constant temperature gradient $G = 33.5$ K/mm by pulling it down at a constant pulling rate $v = 125$ μm/s,

e) rapidly quenched by being pulled down into the Ga-In-Sn liquid metal.

The research of directional solidification was performed at the Faculty of Foundry Engineering, Department of Engineering of Cast Alloys and Composites at the AGH University of Science and Technology in Krakow. The procedure of the experiment is defined in more detail in [7-9]. The directional solidification studies of this alloy are described in [10,11].

Chemical composition of Fe-4.25% C alloy is shown in Table 1.

Considering that overall the dimensions of the leading phase are smaller than the dimensions of wetting phase, it should be stated that the leading phase of the examined alloy is the cementite phase (Fig. 1) [12].

The Figure 1 shows scheme of solid/liquid interface of quasi-regular Fe-4.25% C eutectic alloy. The width of the cementite phase lamellae $2S_{Fe3C}$ is smaller than the width of austenite phase (pearlite) $2S_{Fe(\gamma)}$. Therefore, in the studied eutectic alloy, cementite is the leading phase as indicated by convexity of $d_{Fe3C}$ cementite phase [12]. The concave of austenite phase $d_{Fe(\gamma)}$ and convexity of $d_{Fe3C}$ cementite phase are shown.

3. Analysis of eutectic growth according to the Guzik model

The Guzik model [13] comes from the mass diffusion equation:

$$\frac{\partial^2 C}{\partial x^2} + \frac{\partial^2 C}{\partial y^2} + \frac{v}{D} \frac{\partial C}{\partial y} = 0$$

TABLE 1

Chemical composition of Fe-4.25% C alloy [wt. %]
which under specified boundary conditions and mass balance conditions at the s/l interface allows to determine the concentration field in the liquid phase ahead of the s/l interface:

\[ C(x,y) = C_E + \Delta C_\infty + B_0 \exp\left( -\frac{y v}{D} \right) + \sum_{n=1}^{\infty} B_n \cos \left( \frac{n \pi (x - S_{Fe,C})}{\lambda} \right) \exp\left( -\frac{n \pi y}{\lambda} \right) \]

(2)

where:

\[ B_0 = C_0^{Fe-C} \Phi_{Fe,C} - C_0^{Fe(\gamma)} \Phi_{Fe(\gamma)} \]

(3)

\[ B_n = \frac{\lambda}{(n \pi)^2} D C_0 \sin \left( n \pi \Phi_{Fe,C} \right) \]

(4)

\[ C_0 = C_0^{Fe-C} + C_0^{Fe(\gamma)} \]

(5)

Guzik [13], for growth analysis, attached x-y coordinate system at the triple point of the solid/liquid interphase. It moved in the direction of the y axis.

A constant eutectic growth rate \( v \) and a constant temperature gradient \( G \) in the liquid at the s/l interface were assumed. To describe the s/l interface shape of cementite and austenite phases, an even square function was used, which was symmetrical in relation to the y axis:

\[ f(x) = ax^2 + bx + c \]

(6)

This function was chosen, due to the analysis of Magnin and Kurz [14] study.

Boundary conditions for the \( Fe_3C \) – faceted phase were determined:

\[ f_1(S_{Fe,C}) = d_{Fe,C} \]

(7)

\[ f_1(0) = 0 \]

(8)

\[ \left( \frac{df_1}{dx} \right)_0 = \tan \left( 180^\circ - \theta_{Fe,C} \right) = -\tan \theta_{Fe,C} \]

(9)

\[ \left( \frac{df_1}{dx} \right)_{S_{Fe,C}} = 0 \]

(10)

For the non-faceted phase, the following boundary conditions are given:

\[ f_2(S_{Fe(\gamma)}) = -d_{Fe(\gamma)} \]

(11)

\[ f_2(0) = 0 \]

(12)

\[ \left( \frac{df_2}{dx} \right)_0 = \tan \theta_{Fe(\gamma)} \]

(13)

\[ \left( \frac{df_2}{dx} \right)_{S_{Fe(\gamma)}} = 0 \]

(14)

Conditions given by Eq. (7) and Eq. (11) are related to the value of protrusion of the carbide faceted phase \( d_{Fe,C} \) and the delay of the non-faceted phase \( d_{Fe(\gamma)} \). Further conditions Eq. (8-10) and Eq. (12-14) are a consequence of the shape of the s/l interface adopted. The sought functions \( f_1(x) \) and \( f_2(x) \) for the adopted boundary conditions can be written:

- for the \( Fe_3C \) faceted phase:

\[ f_1(x) = \left( \tan \theta_{Fe(\gamma)} - \frac{8 d_{Fe,C}}{\Delta \theta_{Fe,C}} \right) \left( x + S_{Fe,C} \right)^2 + d_{Fe,C} \]

(15)

- for the \( Fe(\gamma) \) nonfaceted phase:

\[ f_2(x) = \left( \frac{8 d_{Fe(\gamma)}}{\Phi_{Fe(\gamma)}^2} - \frac{3 \tan \theta_{Fe(\gamma)}}{\Phi_{Fe(\gamma)}} \right) \left( x - S_{Fe(\gamma)} \right)^2 - d_{Fe(\gamma)} \]

(16)

The following nonisothermal coupling condition is given:

\[ \frac{1}{\Delta T_F} \int_0^{S_{Fe(\gamma)}} \left[ \Delta T_F(x) + \Delta T_c(x) + Gf_1(x) \right] dx = \frac{1}{S_{Fe(\gamma)}} \int_0^{S_{Fe(\gamma)}} \left[ \Delta T_F(x) + \Delta T_c(x) + Gf_2(x) \right] dx = \Delta T \]

(17)

The components of general undercooling \( \Delta T \), \( \Delta T_c \) components associated with the diffusion process, and the \( \Delta T_c \) solidification front curvature were adopted according to the Jackson-Hunt theory, [15,16].

Further components of the equation (17) are as follows:

\[ \frac{1}{S_{Fe(\gamma)}} \int_0^{S_{Fe(\gamma)}} \Delta T_F(x) dx = \frac{1}{S_{Fe(\gamma)}} \int_0^{S_{Fe(\gamma)}} \Delta T_c(x) dx = \frac{2 \Gamma_{Fe(\gamma)} \sin \theta_{Fe(\gamma)} \Phi_{Fe(\gamma)}^2}{\Phi_{Fe(\gamma)}^2} \]

(18)

\[ \frac{1}{S_{Fe,C}} \int_{S_{Fe,C}}^{S_{Fe(\gamma)}} \Delta T_c(x) dx = \frac{2 \Gamma_{Fe(\gamma)} \sin \theta_{Fe,C} \Phi_{Fe,C}}{\Phi_{Fe,C}^2} \]

(19)
For the studied directionally solidified Fe-4.25% C eutectic alloy, the relationship between interphase (interlamellar) spacing $\lambda$ and growth rate $v$, is given by the formula from [12]:

$$\lambda = -0.0405 v^{-0.5} + 11.499$$

Substituting equation (28) into equation (26):

$$d_{Fe,C} = \frac{15 \Phi_{Fe,C}^2}{7G(-0.0405v^{-0.5} + 11.499)^2 \Phi_{Fe,C}^2 + 240 \Gamma_{Fe,C}}$$

Equations (26) and (27) define the protrusion of the leading phase (cementite) and the delay of the wetting phase (austenite), respectively. Eq. (29) shows the relationship of protrusion of the leading cementite phase between growth rate for studied directionally solidified Fe-4.25% C eutectic alloy.

4. Analysis of eutectic growth according to the Wołczyński model

Observation of the concave-convex front of solidification and its scheme (Fig. 2) shows that the lamellae of both phases are almost equal in width, or that the width of the cementite phase is slightly smaller. Therefore, assumptions found in the literature, [17,18] can be used to analyse the growth of the researched cast iron.

Considering the facts that the local mass balance is met for the condition $z = 0$ in the case of a wider Fe($\gamma$) phase lamellar, and assuming that $z = d$ for the narrower Fe$_3$C phase lamellar, the boundary mass balance is also considered at the same location.

The existence of protrusion $d$ has been disclosed and described theoretically, [19-21]. It has been experimentally confirmed that usually the finer (smaller dimensionally) phase is the leading phase, [20,21]. This corresponds to the analysis of the local mass balance shown in the work, [17] by Equations (31), (32), (33) and Eq. (33*). Accordingly, protrusion is only observed for the phase with smaller (narrower) lamellar.

In order to determine the value of the advance parameter for the examined eutectics Fe($\gamma$) – 4.25% C, the Wołczyński equation from [17] was used. It allows to define the phase protrusion $d$ for the leading phase for own Bridgman experiment.

Figure 2 shows the protrusion scheme for the solid/liquid interface described by the experiment performed in [7,8]. For this
condition, there is a condition for the nonisothermal s/l interface of regular eutectics:

\[
\Delta T_{Fe(\gamma)} \neq \Delta T_{Fe,C}
\]  

(30)

\[
C_0^{Fe(\gamma)}(S_{Fe,C},0) = C_0^{Fe(\gamma)}(S_{Fe(\gamma)},0) - C_E < 0
\]  

(31)

\[
C_0^{Fe,C}(S_{Fe,C},0) = C_0^{Fe,C}(S_{Fe,C},0) - C_E > 0
\]  

(32)

For the stationary eutectic growth, the diffusion equation is, [16]:

\[
\frac{\partial^2 C}{\partial x^2} + \frac{\partial^2 C}{\partial z^2} + \frac{\nu}{D} \frac{\partial C}{\partial z} = 0
\]  

(33)

The solution to Eq. (33) can be given as:

\[
\delta C(x,z) = X(x)Z(z)
\]  

(34)

with the coordinate system attached to the s/l interface just at the middle of the Fe(\gamma) – phase lamella (Fig. 2).

New boundary condition has been inserted in the current description:

\[
\delta C(S_{Fe(\gamma)},z) = C(S_{Fe(\gamma)},z) - C_E = 0
\]  

(35)

The Jackson and Hunt theory [15] does not consider Eq. (35). Nevertheless, the assumption given by Eq. (35) does not allow a discontinuity of solute undercooling (constitutional undercooling) to appear. This results in micro-field of the temperature at the s/l interface. Therefore,

\[
Z(z) = \exp \left[ - \frac{\nu}{2D} \left( \frac{\nu^2}{4D^2} + \omega^2 \right) z \right]
\]  

(36)

\[
X(x) = A \cos(\omega x) + B \sin(\omega x)
\]  

(37)

The other boundary conditions are like the ones used in the Jackson and Hunt theory:

\[
\frac{\partial C}{\partial x} = 0 \text{ for } x = 0, \text{ and } x = S_{Fe(\gamma)} + S_{Fe,C}
\]  

(38)

\[
\frac{\partial C}{\partial z} = \frac{\nu C_0^S}{D} \text{ for } S = Fe(\gamma), Fe_3C, z = 0, 0 \leq x < S_{Fe(\gamma)}, S_{Fe(\gamma)} < x \leq S_{Fe(\gamma)} + S_{Fe,C}
\]  

(39)

After some transformations, and with the plane s/l interface applied, the description of the solute micro-field ahead of the s/l interface is:

A) For the Fe(\gamma) – eutectic phase, that is for \( x \in [0, S_{Fe(\gamma)}] \), \( z \geq 0 \).

The value of the parameters \( B \) and \( \omega \) is a result of the following condition:

\[
\delta C(x,z) = 0
\]  

(40)

Therefore, the formula: 

\[
-\omega A \sin(\omega 0) + \omega B \cos(\omega 0) = 0
\]  

(41)

Combining Eq. (34), Eq. (37) with Eq. (35) and Eq. (40) the solution to Eq. (33) is:

\[
\delta C(x,z) = \sum_{n=1}^{\infty} A_{2n-1} \cos \left( \frac{(2n-1)\pi x}{2S_{Fe(\gamma)}} \right) \times
\]  

\[
\exp \left[ - \frac{\nu}{2D} \left( \frac{\nu^2}{4D^2} + \frac{(2n-1)\pi}{2S_{Fe(\gamma)}} \right)^2 \right] z
\]  

(42)

where, \( A_{2n-1} \), is constant.

To define the \( A_{2n-1} \) parameter, the following conditions are required:

\[
\frac{\partial \delta C(x,z)}{\partial z} \bigg|_{z=0} = f_{Fe(\gamma)}(x);
\]  

(43)

\[
f_{Fe(\gamma)}(x) < 0, x \in \left[ 0, S_{Fe(\gamma)} \right] f_{Fe(\gamma)}(x) \neq 0
\]  

(44)
The following properties of introduced function $f(x)$ are worth noting:

$$ f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \left( \frac{n \pi x}{2S_{Fe(r)}} \right) $$

$$ f(x) = \frac{1}{2S_{Fe(r)}} \int_{0}^{\infty} f(x) \cos \left( \frac{n \pi x}{2S_{Fe(r)}} \right) dx $$

Assuming:

$$ f(x + 2S_{Fe(r)}) = -f(x) $$

it results in: $a_{2k} = 0, k = 0, 1, 2, ...$ for $n = 2k$

$$ a_{2k-1} = \frac{2S_{Fe(r)}}{S_{Fe(r)}} \int_{0}^{\infty} f(x) \cos \left( \frac{(2k-1) \pi x}{2S_{Fe(r)}} \right) dx $$

$k = 1, 2, ...$ for $n = 2k-1, k = 1, 2, ...$

The Fourier's series for $f(x)$ can be presented as:

$$ f(x) \approx \sum_{k=1}^{\infty} a_{2k-1} \cos \left( \frac{(2k-1) \pi x}{2S_{Fe(r)}} \right) $$

In conclusion, the parameter $A_{2n-1}$ is defined:

$$ A_{2n-1} = \left\{ \begin{array}{ll} \frac{v}{2D} - \frac{v^2}{4D^2} + \frac{(2n-1) \pi}{2S_{Fe(r)}} & \\
\left( \frac{2n-1} {2S_{Fe(r)}} \right)^{2n-1} & \end{array} \right. $$

$$ \times \frac{2S_{Fe(r)}}{S_{Fe(r)}} \int_{0}^{\infty} f_{Fe(r)}(x) \cos \left( \frac{(2n-1) \pi x}{2S_{Fe(r)}} \right) dx $$

$n = 1, 2, ...$

The obtained solution can easily be proved, Eq. (35) and Eq. (42), fulfills the conditions applied to the description:

$$ \frac{\partial \delta C(x,z)}{\partial x} \bigg|_{x=0}^{\infty} = 0 $$

$$ \frac{\partial \delta C(x,z)}{\partial z} \bigg|_{z=0}^{2S_{Fe(r)}} = f_{Fe(r)}(x) $$

$$ = f_{Fe(r)}(-x) $$

$$ = -f_{Fe(r)}(x + 2S_{Fe(r)}) $$

$$ \frac{\partial \delta C(x,z)}{\partial z} \bigg|_{z=0}^{2S_{Fe(r)}} = -f_{Fe(r)}(x + 2S_{Fe(r)}) $$

according to the assumptions:

$$ f_{Fe(r)}(-x) = f_{Fe(r)}(x) $$

$$ f_{Fe(r)}(x + 2S_{Fe(r)}) = -f_{Fe(r)}(x) $$

B) By analogy, for the Fe₃C – faceted eutectic phase:

$$ x \in \left[ S_{Fe(r)}, S_{Fe(r)} + S_{Fe,C} \right], \ z \geq 0 $$

$$ \delta C(x,z) = \sum_{n=1}^{\infty} \left\{ \begin{array}{ll} B_{2n-1} \cos \left( \frac{(2n-1) \pi}{2S_{Fe,C}} \right) \left( x - S_{Fe(r)} - S_{Fe,C} \right) \\
\exp \left[ \frac{-\nu}{2D} \sqrt{ \frac{v^2}{4D^2} + \frac{(2n-1)^2 \pi^2}{2S_{Fe,C}^2} } \right] \right. \right. $$

$$ \times \int_{S_{Fe(r)} - S_{Fe,C}}^{S_{Fe(r)}} f_{Fe,C}(x) \cos \frac{(2n-1) \pi}{2S_{Fe,C}} (x - S_{Fe(r)} + S_{Fe,C}) dx $$

For solidification from [7,8,12]:

$$ \delta C(x,z) = \sum_{n=1}^{\infty} B_{2n-1} \cos \left( \frac{(2n-1) \pi}{2S_{Fe,C}} \right) $$

$$ \times \exp \left( \frac{(2n-1) \pi}{2S_{Fe,C}} z \right) $$

$$ B_{2n-1} = -\frac{4}{(2n-1)^2} \int_{S_{Fe(r)}}^{S_{Fe(r)} + S_{Fe,C}} f_{Fe,C}(x) $$

$$ \times \cos \frac{(2n-1) \pi}{2S_{Fe,C}} (x - S_{Fe(r)} + S_{Fe,C}) dx $$

with:

$$ \frac{\partial \delta C(x,z)}{\partial z} \bigg|_{z=0}^{\infty} = f_{Fe,C}(x), \ x \in \left[ 0, S_{Fe,C} \right] $$

The relationship between $A_{2n-1}$ and $B_{2n-1}$ [17] is:

$$ B_{2n-1} = A_{2n-1} \left( \frac{S_{Fe(r)}}{S_{Fe,C}} \right)^{2n-1}, \ n = 1, 2, ... $$

The solution obtained should be verified using the so-called local mass balance calculation:

$$ S_{Fe(r)} \int_{0}^{\infty} \delta C(x,0) dx + \int_{S_{Fe(r)}}^{S_{Fe(r)} + S_{Fe,C}} \delta C(x,d) dx = 0 $$

Local mass balance, Eq. (59), is fulfilled provided that $d_{Fe,C}$ is taken into account – the protrusion of the leading eutectic phase Fe₃C over the wetting eutectic phase Fe(r). This
theoretical conclusion is justified, as the phase protrusion has been observed experimentally.

Furthermore, according to the assumption of coupled eutectic growth, $\Delta T_{Fe,C} \neq \Delta T_{Fe(\gamma)}$, Eq. (22), the protrusion is to be expected. Eq. (59) results in:

$$
\sum_{n=1}^{\infty} a_{2n-1} \left( \frac{1}{2} \right)^{n-1} \pi = \sum_{n=1}^{\infty} b_{2n-1} \left( \frac{1}{2} \right)^{n-1} \pi \times \exp \left( -\frac{n \pi}{2 \lambda} + \sqrt{\left( \frac{n \pi}{2 \lambda} \right)^2 + \left( \frac{2(n-1)}{D^2 \pi^2} \right)} \right) = 0
$$

(60)

For solidification from [7,8,12]:

$$
\sum_{n=1}^{\infty} a_{2n-1} \left( \frac{1}{2} \right)^{n-1} \pi = \sum_{n=1}^{\infty} b_{2n-1} \left( \frac{1}{2} \right)^{n-1} \pi \times \exp \left( -\frac{n \pi}{2 \lambda} + \sqrt{\left( \frac{n \pi}{2 \lambda} \right)^2 + \left( \frac{2(n-1)}{D^2 \pi^2} \right)} \right) = 0
$$

(61)

Figure 2 shows interlamellar (interphase) spacing $\lambda$ as a geometric parameter as follows:

$$
\lambda = 2 \left( S_{Fe,C} + S_{Fe(\gamma)} \right)
$$

(62)

thus:

$$
S_{Fe(\gamma)} = \frac{\lambda}{2} - S_{Fe,C}
$$

(63)

For the studied directionally solidified Fe-4.25% Ceutetic alloy, the relationship between interphase (interlamellar) spacing $\lambda$ and growth rate $v$ is given by the formula from [12]:

$$
\lambda = -0.0405v^{-0.5} + 11.499
$$

(64)

thus:

$$
S_{Fe(\gamma)} = \frac{-0.0405v^{-0.5} + 11.499}{2} - S_{Fe,C}
$$

(65)

Substituting Eq. (65) to formula Eq. (61):

$$
\sum_{n=1}^{\infty} a_{2n-1} \left( \frac{1}{2} \right)^{n-1} \pi \times \left\{ \frac{\left( -0.0405v^{-0.5} + 11.499 \right)}{2} - S_{Fe,C} \right\} \times \exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) = 0
$$

(66)

The above equation will be met if for each $n$:

$$
A_{2n-1} = 0 \quad \text{or} \quad \left( \frac{1}{2} \right)^{n-1} = 0, \quad \text{which is only met for} \quad n = \infty; \quad \text{or}:
$$

$$
\frac{1}{2} \left( -0.0405v^{-0.5} + 11.499 \right) \times S_{Fe,C}
$$

(67)

$$
\exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) = 1
$$

(68)

after rearrangements:

$$
\exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) = 1
$$

(69)

which reduces to:

$$
\frac{-0.02025v^{-0.5} + 5.7495 - S_{Fe,C}}{S_{Fe,C}} \times \exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) = 1
$$

(70)

logarithmized:

$$
\ln \left( \frac{-0.02025v^{-0.5} + 5.7495 - S_{Fe,C}}{S_{Fe,C}} \times \exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) \right) = \ln(1)
$$

(71)

the sum of logarithms on both sides was obtained:

$$
\ln \left( \frac{-0.02025v^{-0.5} + 5.7495 - S_{Fe,C}}{S_{Fe,C}} \right) + \ln \left( \exp \left( -\frac{(2n-1)\pi}{2S_{Fe,C}} \right) \right) = 0
$$

(72)

which reduces to:

$$
\ln \left( \frac{-0.02025v^{-0.5} + 5.7495 - S_{Fe,C}}{S_{Fe,C}} \right) + \frac{(2n-1)\pi}{2S_{Fe,C}} = 0
$$

(73)

rearranged to:

$$
\frac{(2n-1)\pi}{2S_{Fe,C}} = \ln \left( \frac{-0.02025v^{-0.5} + 5.7495 - S_{Fe,C}}{S_{Fe,C}} \right)
$$

(74)
eventually resulting in:

\[
d = \frac{2S_{FeC} \ln \left( \frac{-0.02025v^{-0.5} + 5.7495 - S_{FeC}}{S_{FeC}} \right)}{(2n-1)\pi} \quad (74)
\]

Eq. (74) defines protrusion \( d \) of leading cementite phase obtained according to Wołczyński model.

5. Concluding remarks

After rapid quenching of directionally solidified of Fe-4.25% C eutectic alloy [7,8,12], protrusion and delay of eutectic phases were observed. Protrusion and delay of these phases ensure a mass balance at the solid/liquid interface of the growing eutectic alloy Fe-4.25% C.

Using current mathematical analysis, it is possible to calculate the protrusion of leading cementite phase and delay of wetting austenite phase.

The mass diffusion equation was used in both models. In each model, different parameters describing the solidifying alloy were used. Different boundary conditions and mass balance conditions at the solid/liquid border were also determined. This allowed to present the concentration field in the liquid phase ahead of the solid/liquid interface.

The analysis, according to Guzik model, showed that equation (29) presents the relationship between protrusion \( d_{FeC} \) of leading phase and eutectic growth rate \( v \). Another relationship of these parameters shows the equation (74) according to Wołczyński model.

In the Guzik model, the total protrusion \( d \) is the sum of the protrusion \( d_{FeC} \) of leading cementite phase Eq. (26) and the delay \( d_{Fe(γ)} \) of wetting austenite phase Eq. (27). In the Wołczyński model, the calculated protrusion \( d \), Eq. (74), is a protrusion of leading phase (cementite) over the wetting phase (austenite).

Equation (29) from the Guzik model shows that the function describing the relationship between protrusion of cementite \( d_{FeC} \) and growth rate \( v \) is polynomial. Variable \( v \) (growth rate), in this polynomial function, is in a base of multiple exponential expressions with different exponents.

In the Eq. (74) obtained using the Wołczyński model, the mathematical relationship between protrusion \( d \) and growth rate \( v \) is logarithmic.

The protrusion of cementite parameters obtained in the calculations of these two models cannot be compared. The nature of protrusion for equation (29) and (74) is different. The behaviour of the protrusion of leading parameter is different in both models.
